Lecture #12 – Thursday, October 16, 2003

DIFFERENTIATION

- What is the slope of the secant line \( P Q \)?

\[
\frac{f(c+h) - f(c)}{(c+h) - c} = \lim_{h \to 0} \frac{f(c+h) - f(c)}{h}.
\]

- Idea: Get the slope of the tangent line as a limit of slopes of secant lines.
- The slope of the tangent line at \( x = c \) “ought” to be \( \lim_{h \to 0} \frac{f(c+h) - f(c)}{h} \).

**Example**

\[ f(x) = |x| \text{ at } x = 0 \]

- This DOESN’T have a well defined tangent line

**Definition**

- \( f \) is differentiable at \( x = c \) if the limit \( \lim_{h \to 0} \frac{f(c+h) - f(c)}{h} \) exists. If it does, we call it the derivative of \( f \) at \( c \) and we denote it by \( f'(c) \).

**Geometrically**

- \( f'(c) \) is the slope of the tangent line going through \( (c, f(c)) \).
- What is the equation for tangent line? \( y - f(c) = f'(c)(x - c) \)
Example

- For function \( f(x) = x^2 \), the derivative of \( f \) at \( c = 2 \) is \( f'(2) = \lim_{h \to 0} \frac{(2+h)^2 - (2)^2}{h} = 4 \).
- The derivative of \( f \) is itself a function – for \( f(x) = x^2 \) repeat the same calculation for any value of \( c \).
- \[ f'(c) = \lim_{h \to 0} \frac{f(c+h) - f(c)}{h} = \lim_{h \to 0} \frac{(c+h)^2 - (c)^2}{h} = \lim_{h \to 0} \frac{c^2 + 2ch + h^2 - c^2}{h} = 2c \]
- At any fixed value of \( x \), \( f'(x) = 2x \).

Definition

- The derivative of \( f \) is a function, denoted \( f' \), and \( f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \), if it exists.

Terminology

- To differentiate a function is to find the derivative.
- Notice: The function \( f \) has to be defined in the interval \( (a-d, a+d) \) in order for \( f'(x) \) to be defined.

Example

- Actually, even if \( f \) is continuous on \( (a-d, a+d) \), it doesn’t mean \( f'(x) \) is defined.
- Consider \( f(x) = |x|, c = 0 \)

Theorem

- If \( f \) is differentiable at \( x \), the \( f \) is continuous.
- "Being differentiable is ‘better’ than being continuous.”
- Proof:
  - Because \( f \) is differentiable at \( x \), \( \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} = f'(x) \)
  - \( \lim_{h \to 0} (f(x+h) - f(x)) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \cdot h = f'(x) \cdot 0 = 0 \)
  - So \( f \) is continuous.

Differentiation Rules

Building Blocks

- If \( f(x) = c \) (a constant function), then \( f'(x) = 0 \) for all \( x \).
- If \( f(x) = x \), then \( f'(x) = 1 \) for all \( x \).
Theorem: Sums and Scalar Multiples

- Let \( f, g \) be differentiable at \( x \) and \( \alpha \) a constant.
- Then \( (f + g) \) and \( \alpha f \) are differentiable, then
  - \( (f + g)'(x) = f'(x) + g'(x) \)
  - \( (\alpha f)'(x) = \alpha f'(x) \)
- Proof:
  
  \[
  (f + g)'(x) = \lim_{h \to 0} \frac{(f + g)(x+h) - (f + g)(x)}{h} \\
  = \lim_{h \to 0} \frac{f(x+h) + g(x+h) - f(x) - g(x)}{h} \\
  = f'(x) + g'(x)
  \]

Example

- If \( f(x) = 10x \), \( f'(x) = 10 \)

Theorem: Differences and Linear Combinations

- From the Sums and Scalar Multiples rule,
  - \( (f - g)'(x) = f'(x) - g'(x) \)
  - \( (\alpha_1 f_1 + \alpha_2 f_2 + \ldots + \alpha_n f_n)'(x) = \alpha_1 f_1'(x) + \alpha_2 f_2'(x) + \ldots + \alpha_n f_n'(x) \)

Theorem: Product Rule

- If \( f \) and \( g \) are differentiable at \( x \), then \( f \cdot g \) is differentiable and \( (f \cdot g)'(x) = f'(x) \cdot g(x) + f(x) \cdot g'(x) \)
- Proof:
  
  \[
  (f \cdot g)'(x) = \lim_{h \to 0} \frac{(f \cdot g)(x+h) - (f \cdot g)(x)}{h} \\
  = \lim_{h \to 0} \frac{f(x+h) \cdot g(x+h) - f(x) \cdot g(x)}{h} \\
  = \lim_{h \to 0} \frac{f(x+h) \cdot g(x+h) - f(x) \cdot g(x+h) + f(x) \cdot g(x+h) - f(x) \cdot g(x)}{h} \\
  = f'(x)g(x) + f(x)g'(x)
  \]

Because \( f, g \) are differentiable, they are continuous.
- \( f'(x)g(x) + f(x)g'(x) \)

Theorem: Power Rule

- Using the Product Rule, we derive the Power Rule.
- For \( n > 0, n \in \mathbb{Z} \), if \( f(x) = x^n \), then \( f'(x) = nx^{n-1} \).
- Proof (by induction):
  - True for \( k = 1 \)
  - Assume \( (x^k)' = kx^{k-1} \). Prove for \( k + 1 \):
\[
\left(x^{k+1}\right)' = \left(x^k \cdot x\right)' = kx^{k-1} \cdot x + x^k \cdot 1 = kx^k + x^k = (k+1)x^k
\]

Examples

\[
f(x) = x^2 + 10x^3 - 3x^5
\]
\[
f'(x) = 2x + 30x^2 - 15x^4
\]

Lecture # 14 – Thursday, October 23, 2003

Theorem: Reciprocal Rule

- If \( g \) is differentiable at \( x \), \( g(x) \neq 0 \), then \( \frac{1}{g} \) is also differentiable, and \( \left( \frac{1}{g} \right)'(x) = -\frac{g'(x)}{g(x)^2} \).

Proof:

\[
\lim_{h \to 0} \frac{1}{g(x+h)} + \frac{1}{g(x)} \hfill \\
\hfill = \lim_{h \to 0} \frac{1}{h} \left[ \frac{g(x) - g(x+h)}{g(x+h) \cdot g(x)} \right] \\
\hfill = \lim_{h \to 0} \left[ \frac{1}{g(x+h) \cdot g(x)} \right] \left[ -\frac{g(x+h) - g(x)}{h} \right] \\
\hfill = -\frac{g'(x)}{g(x)^2}
\]

Theorem: General Power Rule (for any exponent)

- For \( n < 0 \), \( (x^n)' = nx^{n-1} \).

Proof:

- Let \( p(x) = x^n = \frac{1}{g(x)} \), and let \( g(x) = x^{-n}, n \) is positive.
- By previous Power Rule, we know \( g'(x) = (-n)x^{-n-1} \).
- So \( p'(x) = \frac{nx^{-n-1}}{x^{-2n}} = nx^{-n-1} \cdot x^{-2n} = nx^{-n-1} \).
- Last case: \( n = 0 \).
  - \( p(x) = x^0 = 1 - \) constant.
  - \( p'(x) = 0x^{0-1} = 0 \).

Theorem: Quotient Rule

- If \( f \) is differentiable at \( x \) and \( g \) is differentiable at \( x \), \( g(x) \neq 0 \), the \( \frac{f}{g} \) is differentiable at \( x \) and

\[
\left( \frac{f}{g} \right)'(x) = \frac{f'(x)g(x) - g'(x)f(x)}{g(x)^2}.
\]
• Proof:
  • Use the fact that \( \frac{f}{g} = f \cdot \frac{1}{g} \).

\[
\left( \frac{f}{g} \right)'(x) = \left( f \cdot \frac{1}{g} \right)'(x)
\]

\[
= f'(x) \cdot \frac{1}{g}(x) + f(x) \cdot \left( \frac{1}{g} \right)'(x)
\]

\[
= f'(x) \cdot \frac{1}{g}(x) - f(x)g'(x)
\]

\[
= \frac{f'(x)g(x) - f(x)g'(x)}{g(x)^2}
\]

Example

1) Find where the tangent line to the graph of \( y = x^3 - \frac{16}{x} \) is horizontal.

  • Tangent line horizontal \( \Rightarrow \) derivative = 0.
  • What is \( y' \)? \( y' = 2x + \frac{16}{x^2} \)
  • So \( 2x + \frac{16}{x^2} = 0 \Rightarrow \frac{x^3 + 8}{x^2} = 0 \Rightarrow x = -2 \).
  • So the tangent line is horizontal at the point \((-2, 12)\).

2) Find derivative: \( f(x) = \frac{x^3 + 1}{2 + \frac{3}{x}} \) at \( x = 3 \).

\[
f'(x) = \frac{3x^2 \cdot \left( 2 + \frac{3}{x} \right) - (x^3 + 1) \left( -3x^{-2} \right)}{ \left( 2 + \frac{3}{x} \right)^2 }
\]

Leibniz Notation

• \( y \) is a “function” of \( x \) – we used to write \( y = f(x) \).
  • \( y = \) “function”
  • \( x = \) “variable”

• Derivative of \( y \) with respect to (w.r.t.) \( x = \frac{dy}{dx} \).

• Note: Could also be \( \frac{du}{ds} \cdot \frac{dt}{dy} \).

Higher Derivatives

• Second derivative of \( f \) is \( (f')' = f'' \).
Third derivative of \( f \) is \((f')' = f''\).

The \( r \)th derivative of \( f \) is \( f^{(r)} \).

In the Leibniz notation, \( \frac{d}{dx} \left[ \frac{dy}{dx} \right] = \frac{d^2 y}{dx^2} \cdot \frac{d}{dx} \left[ \frac{d^2 y}{dx^2} \right] = \frac{d^3 y}{dx^3} \ldots. \)

**Examples**

1) Find the 3rd derivative of \( y = 3x^3 + 2x + 15 \).

- \( \frac{dy}{dx} = 9x^2 + 2 \)
- \( \frac{d^2 y}{dx^2} = 18x \)
- \( \frac{d^3 y}{dx^3} = 18 \)

2) Find \( \frac{d^2}{dx^2} \left[ \left( x^2 - 3x \right) \cdot \frac{d}{dx} \left[ x + x^{-1} \right] \right] \)

- \( \frac{d^2}{dx^2} \left[ \left( x^2 - 3x \right) \cdot \frac{d}{dx} \left[ x + x^{-1} \right] \right] \)
- \( \frac{d^2}{dx^2} \left[ \left( x^2 - 3x \right) \cdot \frac{d}{dx} \left[ x + x^{-1} \right] \right] \)
- \( = \frac{d^2}{dx^2} \left[ x^2 - 3x \right] \cdot \frac{d}{dx} \left[ 1 - x^{-2} \right] \)
- \( = \frac{d^2}{dx^2} \left[ x^2 - 3x \right] \cdot \frac{d}{dx} \left[ 1 - x^{-2} \right] \)
- \( = \frac{d^2}{dx^2} \left[ x^2 - 3x \right] \cdot \frac{d}{dx} \left[ 1 - x^{-2} \right] \)
- \( = 2 + 6x^{-3} \)

**Chain Rule**

- \((f \circ g)(x) = f'(g(x)) \cdot g'(x)\)

**Derivative as a Rate of Change**

- \( g'(c) = \frac{g(x) - g(c)}{x - c} \)
- \( g(x) - g(c) = g'(c)(x - c) \)
IDEA BEHIND THE CHAIN RULE

- Suppose we have \( g'(c) \) and \( f'(g(c)) \). We want to ask about the rate of change of composition \( f \circ g \).

For the Chain Rule, we want to know if \( x \) is close to \( c \), what is \( f(g(x)) - f(g(c)) \)?

What we know:
- Change \( x - c \) → \( g'(c)(x-c) \) → \( g(x) - g(c) \) changing.
- Change \( g(x) - g(c) \) → \( f'(g(c))(g(x) - g(c)) \) → \( f(g(x)) - f(g(c)) \) change in \( f \).
- Put together: change \( x - c \) → \( f'(g(c)) \cdot g'(c)(x-c) \).

In Leibniz notation, the Chain Rule looks like:
- Suppose \( y = f(u) \) and \( u = g(x) \).
- The Chain Rule says: \( \frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} \).

Example: Checking the Chain Rule

- \( y = u \quad u = x^2 \) \( y = x^6 \)
- \( \frac{dy}{dx} = 6x^5 \)
- \( \frac{dy}{du} = 3u^2 \), \( \frac{du}{dx} = 2x^2 \). So the Chain Rule says \( 6x^5 = 3(x^2)^2 \cdot 2x = 6x^5 \)

Warning: When using the Chain Rule, have to substitute \( u \) as a function of \( x \).

Another way to write the Chain Rule:
- \( y = f(u) \), \( u = u(x) \)
- \( \frac{d}{dx}[f(u(x))] = f'(u(x)) \cdot \frac{du}{dx} \)

Example

- \( \frac{d}{dx}[(x^3-x+1)^{100}] \)
- \( f(u) = u^{100}, \quad f'(u) = 100u^{99} \)
- \( u(x) = x^3 - x + 1, \quad u'(x) = 3^2 - 1 \)
- \( \frac{d}{dx}[(x^3-x+1)^{100}] = 100(x^3-x+1)^{99}(3x^2-1) \)
By the way, can “keep going” – ex: \( \frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{ds} \cdot \frac{ds}{dx} \)

Example

- \( y = \left[ 1 + (2 + 3x)^5 \right]^3 \)
- \( s(x) = 2 + 3x \)
- \( u = 1 + s^5 \)
- \( y = u^3 \)

\[
\frac{dy}{dx} = 3 \left[ 1 + (2 + 3x)^5 \right]^2 \cdot 5(2 + 3x)^4 \cdot 3
\]

**Theorem: Chain Rule**

- If \( g \) is differentiable at \( x \), \( f \) is differentiable at \( g(x) \), then \( f \circ g \) is differentiable at \( x \), and

\[
(f \circ g)'(x) = f'(g(x)) \cdot g'(x).
\]

- Reminder: Another equivalent way define derivate of \( f \) at \( x \) is

\[
\lim_{t \to x} \frac{f(t) - f(x)}{t - x}.
\]

- Idea of proof:
  - We want to compute

\[
\frac{f(g(t)) - f(g(x))}{t - x} = \frac{f(g(t)) - f(g(x))}{g(t) - g(x)} \cdot \frac{g(t) - g(x)}{t - x}
\]
  - Problems:
    - \( \frac{f(g(t)) - f(g(x))}{g(t) - g(x)} \) is not quite the definition of \( f'(g(x)) \).
    - \( \frac{g(t) - g(x)}{t - x} \) might not be defined if \( g(t) = g(x) \).

- Real proof:
  - Define \( F(g) = \begin{cases} f(y) - f(g(x)) & \text{if } y \neq g(x) \\ f'(g(x)) & \text{if } y = g(x) \end{cases} \)
  - Because the definition of \( F \) and \( f \) is differentiable at \( g(x) \), \( \lim_{y \to g(x)} F(y) = F(g(x)) = f'(g(x)) \).
  - Notice: For all \( t \neq x \),

\[
\frac{f(g(t)) - f(g(x))}{t - x} = F(g(x)) \cdot \frac{g(t) - g(x)}{t - x}
\]
  - \( F \circ g \) is continuous at \( x \) because \( g \) is continuous (since differentiable), as we take \( \lim_{t \to x} \),

\[
\text{LHS} = (f \circ g)'(x), \quad \text{RHS} = f'(g(x)) \cdot g'(x).
\]
Lecture #15 – Tuesday, October 28, 2003

MORE ON DERIVATIVES AS A RATE OF CHANGE

- The derivative (the slope of the tangent line) has an interpretation as the “instantaneous” rate of change of \( f(x) \) at \( x = c \).

- Note:
  - If \( f'(x) > 0 \), \( f \) is increasing around \( x \).
  - If \( f'(x) < 0 \), \( f \) is decreasing around \( x \).
  - If \( f'(x) = 0 \), \( f \)'s rate of change is 0 around \( x \).

Example

Find the rate of change of the area \( A \) of a circle which respect to radius \( r \), when the radius is 3.

- \( A(r) = \pi r^2 \)
- \( \frac{dA}{dr} = 2\pi r \)
- When \( r = 3 \), \( \frac{dA}{dr} = 6\pi \).

Common Applications: Position \( x(t) \) as a function of time

- If \( x(t) \) is a position as a function of time:
• The way we usually draw it:

\[ x \]

\[ t \]

- velocity \( v(t) = \frac{dx}{dt} = x'(t) \)
  - \( v(t) > 0 \) means moving left, \( v(t) < 0 \) means moving right.
- acceleration \( a(t) = \frac{dv(t)}{dt} = x''(t) \)
- speed \( |v(t)| \)

• Using \( x, v, a \), can describe motion in detail:

<table>
<thead>
<tr>
<th>( v(t) )</th>
<th>( a(t) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>+</td>
</tr>
<tr>
<td>+</td>
<td>-</td>
</tr>
<tr>
<td>-</td>
<td>+</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Example: Free Fall In a Gravitational Field

- Galileo figured out the trajectory of an object in free fall: \( x(t) = -\frac{1}{2}gt^2 + v_0t + x_0 \).
  - \( g \) = gravitational constant \( \approx 32 \) ft/sec
  - \( v_0 \) and \( x_0 \) are constants – depend on how the object is moving at \( t = 0 \).
  - What is the position at \( t = 0 \)? \( x(0) = x_0 \) – position of object at \( t = 0 \).
What is the velocity at \( t = 0 \)? \( x'(t) = -gt + v_0 \) and \( x'(0) = v_0 \) – velocity of object at \( t = 0 \).

Example

1) What is the equation of the motion if \( x_0 = 4 \text{ft}, \ v_0 = 0 \) ? When do the ball hit the ground?

- \( x(t) = -16t^2 + 4 \).
- At what time is \( x(t) = 0 \)? Solve for \( t: \ t = \frac{1}{2} \).

2) What is the equation of the motion if \( x_0 = 0, \ v_0 = 64 \text{ft/sec} \) ? When do the ball hit the ground?

- \( x(t) = -16t^2 + 64t \).
- At what time is \( x(t) = 0 \)? \( x(t) = 0 = -16t^2 + 64t \Rightarrow t = 4 \)

To get to the more interesting examples, we will need derivatives of trig functions.

\[
\frac{d}{dx} \sin x = \cos x \quad \frac{d}{dx} \cos x = -\sin x
\]

Lecture #16 – Thursday, October 30, 2003

DIFFERENTIATING THE TRIGONOMETRIC FUNCTIONS

Basic Formulas

1) \( \frac{d}{dx} \sin x = \cos x \)

- Proof: Fix \( x \).

\[
\lim_{h \to 0} \frac{\sin(x + h) - \sin(x)}{h} = \lim_{h \to 0} \frac{\sin(x)\cos(h) + \cos(x)\sin(h) - \sin(x)}{h} = \lim_{h \to 0} \left[ \sin x \left( \frac{\cos(h) - 1}{h} + \cos x \frac{\sin(h)}{h} \right) \right] = \cos x
\]

2) \( \frac{d}{dx} \cos x = -\sin x \)
• Proof: Fix $x$.

$$
\lim_{h \to 0} \frac{\cos(x+h) - \cos(x)}{h} = \lim_{h \to 0} \frac{\cos(x)\cos(h) - \sin(x)\sin(h) - \cos(x)}{h} = \lim_{h \to 0} \frac{\cos(h) - 1}{h} - \lim_{h \to 0} \frac{\sin(h)}{h} = -\sin x
$$

• If you ever forget the formulas, just think about the graphs.

![Graph of sin x and cos x](image)

**The Other Trig Formulas**

• These formulas are derived from $\frac{d}{dx} [\sin x] = \cos x$ and $\frac{d}{dx} [\cos x] = -\sin x$ by using the Quotient or Reciprocal Rule.

$$
\frac{d}{dx} [\tan x] = \frac{\frac{d}{dx} [\sin x]}{\frac{d}{dx} [\cos x]} = \frac{\cos x \cdot \cos x + \sin x \cdot \sin x}{(\cos x)^2} = \frac{1}{(\cos x)^2} = \sec^2 x
$$

$$
\frac{d}{dx} [\sec x] = \frac{d}{dx} [\tan x] = \sec x \cdot \tan x
$$

$$
\frac{d}{dx} [\csc x] = -\csc x \cdot \cot x
$$

$$
\frac{d}{dx} [\cot x] = -\csc^2 x
$$

• Of course, you can use the Chain Rule with the trig functions.

**Examples**

1) $\frac{d}{dx} [1 + \tan x] = 3(1 + \tan x)^2 \cdot (\sec^2 x)$

2) $\frac{d}{dx} [\cos(1 + x + x^2)] = -\sin(1 + x + x^2) \cdot (1 + 2x)$

3) $\frac{d}{dx} [\tan(\sec x)] = \sec^2 (\sec x) \cdot \sec x \tan x$
Example: Mass on a pendulum

The motion of the pendulum is given by $\theta(t) = a \sin(\omega t + \phi)$ (a, $\omega$, $\phi$ are constants that depend on $L$, $m$, and initial conditions).

- $\theta'(t) = \omega a \cos(\omega t + \phi)$
- $\theta''(t) = -\omega^2 a \sin(\omega t + \phi)$
- $\theta(t)$ satisfy the differential equation $\theta'' = -\omega^2 \theta$.

Implicit Differentiation

Example

Suppose we’re thinking about the points in $\mathbb{R}^2$ satisfying $xy = 1$. We want to know the slope of tangent line at $x = 2$, $y = \frac{1}{2}$.

- Solution 1: Solve explicitly for $y$ in terms of $x$ – i.e. think of $y$ as a function of $x$.
  - $y = \frac{1}{x}$
  - $\frac{dy}{dx} = -\frac{1}{x^2}$
  - So the slope at $\left(2, \frac{1}{2}\right)$ is $-\frac{1}{2}$.

- Solution 2: Don’t bother to solve for $y$.
  - You know, in principle, you could solve for $y$, so you treat the equation $xy = 1$ as a relationship between functions. $xy = 1$. So $x \cdot y(x) = 1$.
  - If two functions are equal, their derivatives are equal.
  - LHS: $y(x) + x \frac{dy}{dx} y(x) + x \frac{dy}{dx} = 0 \Rightarrow \frac{dy}{dx} = \frac{y(x)}{x} = -\frac{1}{x^2}$
  - RHS: 0

- In general, when you do implicit differentiation, do the following:
  - Work with the equation (relationship between $x$ and $y$) directly.
  - Differentiate LHS and RHS and these derivatives must be equal. Treat $y$ as a function of $x$ (which is, in principle).
  - Solve for $\frac{dy}{dx}$ – in general, it will be an expressing in both $x$ and $y$.

Example

Think about the curve in $\mathbb{R}^2$ specified by $x^3 + y^3 - 3xy = 0$. Find $\frac{dy}{dx}$ for a point on this curve.

- LHS: Treating $y = y(x)$ as a function of $x$.
- Differentiating, $3x^2 + 3y^2 \frac{dy}{dx} + \left(-3y + (-3x) \frac{dy}{dx}\right) = 0 \Rightarrow \frac{dy}{dx} (3y^2 - 3x) = 3y - 3x^2 \Rightarrow \frac{dy}{dx} = \frac{y - x^2}{y^2 - x}$
• Using implicit differentiation, we can prove the Rational Power Rule: 
\[ \frac{d}{dx} \left[ x^{\frac{p}{q}} \right] = \frac{p}{q} x^{\frac{p}{q} - 1} \], \( p, q \in \mathbb{Z} \).

• Proof:
  - Let \( y = x^{\frac{p}{q}} \) \( \Rightarrow y^q = x^p \).
  - Implicit differentiation: \( q y^{q-1} \frac{dy}{dx} = p x^{p-1} \) (by usual Power Rule for \( \mathbb{Z} \)).
  - \[ \frac{dy}{dx} = p x^{p-1} \cdot \frac{1}{q} y^{1-q} = \frac{p}{q} x^{p-1} \cdot \left( x^{\frac{p}{q}} \right)^{1-q} = \frac{p}{q} x^{p-1} x^{\frac{p}{q} - 1} = \frac{p}{q} \]

**MORE ON RATES OF CHANGE (RELATED RATES)**

• Variation on the same theme:
  - We’ll have two variables related by an equation, both are functions of \( t \).
  - When we differentiate, we’ll get a relationship between the derivatives \( \frac{dx}{dt} \) and \( \frac{dy}{dt} \).

**Example**
The volume of a spherical balloon is related to radius. If the radius is expanding uniformly at 2 cm/min, how fast is the volume changing when radius is 5 cm?

\[
V = \frac{4}{3} \pi r^3 \\
V = V(t) \\
r = r(t) \\
\frac{dV}{dt} = 4 \pi r^2 \frac{dr}{dt} = 4 \pi (5)^2 (2) = 200 \pi \text{cm}^3/\text{min}
\]

**Example**
Bead moving along a wire which is on the curve \( y = x^2 + 2 \). Given \( \frac{dx}{dt} \), how fast is the height changing when \( x = 2 \)?

**Steps:**
1) Draw picture.
2) Know: \( \frac{dx}{dt} \).
3) Want: \( \frac{dy}{dt} \).
4) What is the relationship? \( y = x^2 + 2 \).
5) Implicitly differentiate: \( \frac{dy}{dt} = 2x \frac{dx}{dt} = 4 \).
Example

Draw at the bottom of the ladder, \( \frac{dx}{dt} = \frac{1}{2} \text{ m/min} \). How fast is \( \theta \) changing when the top of ladder is 8m from the floor?

[Diagram of a ladder with labels]

- Know: \( \frac{dx}{dt} \).
- Want: \( \frac{d\theta}{dt} \).
- Relationship: \( \cos \theta = \frac{x}{10} \)

\[-\sin \theta \frac{d\theta}{dt} = \frac{1}{10} \frac{dx}{dt} \Rightarrow -\frac{8}{10} \frac{d\theta}{dt} = \frac{1}{10} \frac{dx}{dt} \Rightarrow \frac{d\theta}{dt} = -\frac{1}{16}.\]

Lecture #17 – Tuesday, November 4, 2003

MEAN VALUE THEOREM AND APPLICATIONS

Preview

1) Optimization problems: These show up in economics, physics, etc.
   - Example: If a cylinder is circumscribed in a cone, then what is the maximum volume possible of such a cylinder?

[Diagram of a cone with a cylinder circumscribed]

2) Graph sketching:
   - Example: Sketch the graph of the function \( f(x) = \frac{1}{4} x^4 - 2x^2 + \frac{7}{4} \).
   - Idea: Use qualitative the right information (ex: is the function increasing or decreasing, etc.). Some things you evaluate exactly (ex: \( x, y \) intercepts, max/min values).

THE MEAN VALUE THEOREM

- This is a theorem relating the derivative of a function with its end-point values \( f(a) \) and \( f(b) \).
If a theorem is differentiable on \((a, b)\) and \(f\) is continuous on \([a, b]\), there is at least one point \(c\) in \((a, b)\) so that
\[
f'(c) = \frac{f(b) - f(a)}{b - a} = \text{slope of line between } (a, f(a)) \text{ and } (a, f(b)).
\]

**Warning:** The function must be differentiable on \((a, b)\).

**Warning:** The function must also be continuous on \([a, b]\).

**PROVING THE MEAN VALUE THEOREM**

**Lemma**
- Let \(f\) be differentiable at \(x\).
- If \(f'(x_0) > 0\), then \(f(x_0 - h) < f(x_0) < f(x_0 + h)\) for \(h\) sufficiently small, \(h > 0\).
- If \(f'(x_0) < 0\), then \(f(x_0 - h) > f(x_0) > f(x_0 + h)\) for \(h\) sufficiently small, \(h > 0\).
- **Proof:**
  - We know that \(\lim_{k \to 0} \frac{f(x_0 + k) - f(x_0)}{k} = f'(x_0) > 0\).
  - Idea: Use \(f'(x_0)\) as your \(\varepsilon\).
  - \(\exists \delta > 0 \text{ s.t. } \forall \delta < h \text{ then } 0 \leq \frac{f(x_0 + k) - f(x_0)}{k} - f'(x_0) < f'(x_0)\), so
    \[-f'(x_0) < \frac{f(x_0 + k) - f(x_0)}{k} - f'(x_0) < f'(x_0)\).
  - Add \(f'(x_0)\): \(0 < \frac{f(x_0 + k) - f(x_0)}{k} < 2f'(x_0)\).
  - If \(0 < k < \delta\), then \(0 < f(x_0 + k) - f(x_0) \Rightarrow f(x_0 + k) > f(x_0)\).
  - If \(-\delta < k < 0\), then \(0 > f(x_0 + k) - f(x_0) \Rightarrow f(x_0 + k) < f(x_0)\).
- Q.E.D.
Rolle’s Theorem

- Basically, the MVT with \( g(a) = g(b) = 0 \).
  
- Let \( g \) be differentiable on \((a, b)\), continuous on \([a, b]\), \( g(a) = 0 = g(b) \).
- Then there is at least one \( c \) in \((a, b)\) where \( g'(c) = 0 \).
- Proof:
  - If \( g \equiv 0 \), then \( g'(c) = 0 \) for all \( c \in (a, b) \).
  - If \( g \neq 0 \), somewhere it has to be positive or negative.
  - Suppose \( g \) is positive somewhere on \((a, b)\).
    - If \( g \) is positive, then because \( g \) is continuous on \([a, b]\), by the EVT \( g \) has to take a max and it takes a max at a point \( c \in (a, b) \).
    - Want to show: \( g'(c) = 0 \).
    - By the lemma, if \( g'(c) > 0 \) or \( g'(c) < 0 \), \( (c, g(c)) \) is not a max. Contradiction.

Lecture #18 – Thursday, November 6, 2003

Example: Application of Rolle’s Theorem

Show that \( f(x) = 2x^3 + 5x - 10 \) has at most one root.
- Suppose it has 2 roots, \( a < b \). \( f(a) = f(b) = 0 \).
- So Rolle’s Theorem says \( \exists c \), \( f'(c) = 0 \).
- \( f'(x) = 6x^2 + 5 > 0 \), never zero! Contradiction!

Mean Value Theorem

- Let \( f \) be continuous on \([a, b]\), differentiable on \((a, b)\), then there exists a \( c \) in \((a, b)\) so that

\[
f'(c) = \frac{f(b) - f(a)}{b - a}.
\]

- Proof: Use Rolle’s Theorem
  - Idea: Subtract off a linear function to “make” \( f \) into a function that satisfies the requirement for Rolle’s Theorem.
  - Note: The equation of the line through \((a, f(a))\) and \((b, f(b))\) is \( y = \frac{f(b) - f(a)}{b - a} (x - a) + f(a) \).
  - Let \( g(x) = f(x) - \left[ \frac{f(b) - f(a)}{b - a} (x - a) + f(a) \right] \).
  - Notice: \( g(b) = g(a) = 0 \).
  - By Rolle’s Theorem, there is a \( c \) in \((a, b)\) where \( g'(c) = 0 = f'(c) - \frac{f(b) - f(a)}{b - a} \).
• So this means that $f'(c) = \frac{f(b) - f(a)}{b - a}$.

Q.E.D.

**Examples: Applications of MVT**

1) Suppose $f$ is continuous on $[a, b]$. You know $f(1) = 3$ and that in $(1,3)$, $1 \leq f'(x) \leq 3$. What is the maximum value of $f(3)$?

• The maximum possible $f(3) = 9$.

• We know by MVT that there is a $c$ in $(1,3)$ such that $1 \leq f'(c) = \frac{f(3) - f(1)}{3 - 1} = \frac{f(3) - 3}{2} \leq 3 \Rightarrow 5 \leq f(3) \leq 9$.

• Max possible $= 9$, min possible $= 5$.

2) Jury duty problem. The facts: She travels 75m in 5sec. The claim: She was going under speed limit of $40\text{km/hr}$ $\approx 11.1\text{m/s}$.

• Somewhere between when she hit the brakes and $t = 5s$.

• She had to be going $15\text{m/s}$ which is already over $40\text{km/hr}$.

**INCREASING AND DECREASING FUNCTIONS**

**Definition**

• A function $f$ is increasing on an interval $I$. If $\forall x_1, x_2$ in $I$, $x_1 < x_2 \Rightarrow f(x_1) < f(x_2)$.

• A function $f$ is decreasing on an interval $I$. If $\forall x_1, x_2$ in $I$, $x_1 < x_2 \Rightarrow f(x_1) > f(x_2)$.
Example

Theorem

- Let $f$ be differentiable on open interval $I$.
  - If $f'(x) > 0$ for all $x \in I$, then $f$ is increasing on $I$.
  - If $f'(x) < 0$ for all $x \in I$, then $f$ is decreasing on $I$.
  - $f'(x) = 0$ for all $x \in I$, then $f$ is constant on $I$.

Proof

- Let $x_1 < x_2$ on $I$. Then by MVT, $\exists c, x_1 < c < x_2$ such that $0 < f'(c) < \frac{f(x_2) - f(x_1)}{x_2 - x_1}$.
- Multiply by $(x_2 - x_1)$: $0 < f(x_2) - f(x_1) \Rightarrow f(x_2) > f(x_1)$.
  
Q.E.D.

- Actually, works for close intervals.

Theorem

- Let $f$ be continuous on $[a,b]$, differentiable on $(a,b)$.
  - If $f'(x) > 0$ on all of $(a,b)$, then $f$ is increasing on $[a,b]$.
  - If $f'(x) < 0$ on all of $(a,b)$, then $f$ is decreasing on $[a,b]$.
  - If $f'(x) = 0$ on all of $(a,b)$, then $f$ is constant on $[a,b]$.

- Note: We already know that if $f(x) = \text{constant}$ on $I$, $f'(x) = 0$ on $I$. This theorem states the converse, so $f$ is constant on $I \iff f'(x) = 0$ on $I$.

Example: Finding intervals of increase/decrease

- $f(x) = x + \frac{1}{x}$
  - $f'(x) = 1 - \frac{1}{x^2}$
  - Increasing when $1 - \frac{1}{x^2} > 0 \Rightarrow 1 > \frac{1}{x^2} \Rightarrow x^2 > 1 \Rightarrow x \in (-\infty,-1) \cup [1,\infty)$.
  - Decreasing when $x^2 < 1 \Rightarrow x \in [-1,0) \cup (0,1]$. 

Page 19 of 38
• Warning: Just because the function is increasing (decreasing) on \( I \) does not mean the derivative is >0 (<0) on \( I \!

  • At 0, \( f'(x) = 0 \), but it is increasing everywhere.

• Warning: \( f \) needs to be differentiable!

\[
\text{AN ASIDE: (WE’LL COME BACK TO THIS NEXT TERM...)}
\]

• Notice: If \( f \) and \( g \) differ by a constant, so \( f(x) = g(x) + c \), then \( f'(x) = g'(x) \).

• The Theorem (Corollary) then says:
  If \( f, g \) are differentiable on \( I \) and if \( f'(x) = g'(x) \) on \( I \), then \( f(x) = g(x) + c \) on \( I \).
  
  • Proof:
    • \( h(x) = f(x) - g(x) \).
    • \( h'(x) = 0 \) on \( I \).
    • So \( h(x) \equiv c \Rightarrow f = g + c \).
Example

Find a function $f$ so that $f' = 2x^2 + 10x + 2$ and $f(0) = 7$.

- A candidate $g(x)$ for $f'$: $g(x) = \frac{2}{3}x^3 + 5x^2 + 2x$.
- This satisfies $g' = f'$. So $f(x) = \frac{2}{3}x^3 + 5x^2 + 2x + 7$. So $c = 7$ to satisfy $f(0) = 7$.

BACK TO MAIN THEME: LOCAL EXTREME VALUES

Definition

- A function $f$ takes on a local maximum at $c$ if $f(x) \leq f(c)$ for $x$ sufficiently close to $c$ ($\exists \delta > 0$ s.t. $x \in (c - \delta, c + \delta)$).
- A function $f$ takes on a local minimum at $c$ if $f(x) \geq f(c)$ for $x$ sufficiently close to $c$.

Example

- Terminology: Local maximum/minimum are called local extrema.

Theorem

- If $f$ takes on a local extreme value at $c \in$ interior of $I$, then either $f'(c) = 0$ or $f'(c)$ DNE.
- Proof:
  - Suppose $f'(c)$ exist.
  - Then if $f'(c) > 0$, by lemma from Rolle’s Theorem, $\exists$ interval $(c - \delta, c + \delta)$ so that for $c - \delta < x_1 < c < x_2 < c + \delta$, $f(x_1) > f(c) < f(x_2)$ so $c$ is not extreme value.
  - Ditto if $f'(c) < 0$. So $f'(c) = 0$.

Q.E.D.

Lecture #19 – Tuesday, November 11, 2003

Definition

- Let $c$ be in $\text{dom}(f)$ where $f'(c) = 0$ or $f'(c)$ DNE. The $c$ is called a critical point.
- Idea: Critical points are candidates for local extreme values.
Examples

1) \( f(x) = -x^2 + 2 \)
   - \( f'(x) = -2x \)
   - The critical point is at \( c = 0 \).

2) \( f(x) = |x - 2| \)
   - The critical point is at \( c = 2 \).

3) \( f(x) = x^3 + 1 \)
   - \( f(x) = 3x^2 \)
   - The critical point is at \( c = 0 \).
   - Once you have a list of critical points, what to do? Figure out whether it’s a local max, local min, or neither.

**Theorem: “First Derivative Test”**

- Suppose \( c \) is a critical point for \( f \), \( f \) is continuous at \( c \). If \( \exists \delta > 0 \) such that:
  - \( f'(x) > 0 \) for all \( x \in (c - \delta, c) \), \( f'(x) < 0 \) for all \( x \in (c, c + \delta) \), then \( c \) is a local max.
  - \( f'(x) < 0 \) for all \( x \in (c - \delta, c) \), \( f'(x) > 0 \) for all \( x \in (c, c + \delta) \), then \( c \) is a local min.
  - \( f'(x) \) is the same sign on both sides, then it’s not a local extreme value.

**Example**

\( f(x) = x^4 - 2x^3 \). Find local min’s and max’s.

- \( f'(x) = 4x^3 - 6x^2 = 2x^2(2x - 3) \)
- Critical points: 0, \( \frac{3}{2} \).

\[
\begin{array}{ccccc}
& - & 0 & - & + \\
f' & | & 0 & | & \frac{3}{2} & | \\
\end{array}
\]

**Theorem: “Second Derivative Test”**

- Suppose \( f'(c) = 0 \) and \( f''(c) \) exists.
  - If \( f''(c) > 0 \), then \( f(c) \) is a local min.
  - If \( f''(c) < 0 \), then \( f(c) \) is a local max.

**Proof:** Case \( f''(c) > 0 \)

- Remember the Lemma for Rolle’s Theorm.
- Then \( \exists \delta > 0 \) for \( c - \delta < x_1 < c < x_2 < c + \delta \). So \( f'(x_1) < f'(c) < f'(x_2) \).
- Since \( f'(c) = 0 \), so \( f'(x_1) < 0 \) and \( f'(x_2) > 0 \).
- FDT tells us \( c \) is a local min.

Q.E.D.
Example

Find local max/min of \( f(x) = 2x^3 - 3x^2 - 12x + 5 \).

- \( f'(x) = 6x^2 - 6x - 12 = 6(x^2 - x - 2) = 6(x-2)(x+1) \).
- Critical points: \( c = 2, -1 \).
- \( f''(x) = 12x - 6 \)
- So 2 is a local min and -1 is a local max.

Lecture #20 – Thursday, November 13, 2003

Definition: Endpoint Extrema

- If \( c \) is an endpoint of a domain of \( f \), \( f \) has an endpoint maximum at \( c \) if \( f(c) \geq f(x) \) for \( x \) close enough to \( c \) and \( x \) in \( \text{dom}(f) \).
- If \( c \) is an endpoint of a domain of \( f \), \( f \) has an endpoint minimum at \( c \) if \( f(c) \leq f(x) \) for \( x \) close enough to \( c \) and \( x \) in \( \text{dom}(f) \).

Absolute Extrema

Definition

- A function \( f \) has an absolute maximum at \( d \) if \( f(d) \geq f(x) \) for all \( x \in \text{dom}(f) \).
- A function \( f \) has an absolute minimum at \( d \) if \( f(d) \leq f(x) \) for all \( x \in \text{dom}(f) \).

Summary

- For \( f \) defined on a closed bounded \( [a, b] \), to find the absolute extrema:
  - Find critical numbers in interior \( c_1, c_2, c_3, \ldots, c_n \).
  - Calculate \( f(a), f(c_1), f(c_2), \ldots, f(c_n), f(b) \).
  - Largest/smallest from above is the absolute maximum/minimum.

Example

\( f(x) = \sin x - \sin^2 x \), domain = \([0, 2\pi]\).

- \( f'(x) = \cos x - 2 \sin x \cos x \)
- Solve: \( 0 = \cos x - 2 \sin x \cos x \iff 0 = \cos x (1 - 2 \sin x) \). So \( \cos x = 0 \Rightarrow x = \frac{\pi}{2}, \frac{3\pi}{2} \) or \( \sin x = \frac{1}{2} \Rightarrow x = \frac{\pi}{6}, \frac{5\pi}{6} \).
- Calculate:
  - \( f(0) = 0 \)
  - \( f\left(\frac{\pi}{6}\right) = \frac{1}{4} \) – absolute maximum
  - \( f\left(\frac{\pi}{2}\right) = 0 \)
• \( f\left(\frac{5\pi}{6}\right) = \frac{1}{4} \) – absolute maximum
• \( f\left(\frac{3\pi}{2}\right) = -2 \) – absolute minimum
• \( f(2\pi) = 0 \)

**Definition/Notation for Unbounded Domain**

1) “As \( x \to \infty, f(x) \to \infty \).”
   - As \( x \) increases without (upper) bound, \( f(x) \) becomes arbitrarily large.
   - For any positive \( M > 0, \exists k > 0 \) so that if \( x \geq k \), then \( f(x) \geq M \).

2) “As \( x \to \infty, f(x) \to -\infty \).”
   - For any positive \( M > 0, \exists k > 0 \) so that if \( x \geq k \), then \( f(x) \leq M \).

3) “As \( x \to -\infty, f(x) \to \infty \).”
   - For any positive \( M > 0, \exists k < 0 \) so that if \( x \leq k \), then \( f(x) \geq M \).

4) “As \( x \to -\infty, f(x) \to -\infty \).”
   - For any positive \( M < 0, \exists k < 0 \) so that if \( x \leq k \), then \( f(x) \leq M \).

- The point: If (1) or (3) happens, no absolute maximum! If (2) or (4), no absolute minimum!
- Warning: Not all functions fit into (1) to (4) – ex: \( f(x) = \sin x \).
- But: For polynomial \( f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_0, a_n \neq 0, n \neq 0 \) one of (1) to (4) **does** happen, and you determine it by looking only at the “leading term” \( a_n x^n \).

**Example**

\[ f(x) = 3x^4 - 5x^3 + 10x \]

- As \( x \to \infty, f(x) \to \infty \). As \( x \to -\infty, f(x) \to \infty \). So no absolute maximum.

**Final Summary: Finding Absolute Extrema**

1) Find critical numbers in interior.
2) If yo have endpoints, check for endpoint extrema.
3) Look at critical numbers and identify local max’s and min’s.
4) If domain is unbounded, look at “behaviour at infinity”.
5) Evaluate \( f \) at local min’s or max’s and endpoint extrema to find the absolute max/min, if it exists.

**Example**

\[ f(x) = 6\sqrt{x} - x\sqrt{x}, \quad \text{dom}(f) = [0, \infty). \]

- \( f'(x) = 3x^{-\frac{1}{2}} - \frac{3}{2} x^{\frac{1}{2}} = 3 \left( \frac{1}{\sqrt{x}} - \frac{\sqrt{x}}{2} \right) = 3 \left( \frac{2-x}{2\sqrt{x}} \right) = 0 \iff \frac{1}{\sqrt{x}} = \frac{\sqrt{x}}{2} \iff x = 4 \)
• FDT: To the left of $x = 2$, $f' > 0$. To the right of $x = 2$, $f' < 0$. So by FDT, $x = 2$ is a local max.
• What is the behaviour as $x \to \infty$? Because $-x\sqrt{x} \to -\infty$ as $x \to \infty$, $f(x) \to -\infty$ as $x \to \infty$. Give up for absolute min.
• Evaluate: $f(0) = 0$, $f(2) = 4\sqrt{2}$. So $4\sqrt{2}$ is the absolute max.

**Optimization Problems**

**Baby Example**

An isosceles triangle has a base of 6 units and height of 12 units. Suppose we have to inscribe a rectangle. what are the dimensions of such a rectangle of maximum area?

![](https://via.placeholder.com/150)

- Area = $2xy$
- Constraint: $(x, y)$ has to be on the line connecting $(0, 12), (3, 0)$: $y = -4x + 12$.

- Replacing $y$: Area = $A(x) = 2x(-4x + 12) = 8(-x^2 + 3x)$.
- Key: Now Area is a function of one variable!
- For the problem, dom$(A) = [0, 3]$.
- $A'(x) = 8(-2x + 3) = 0 \Rightarrow x = \frac{3}{2}$.
- $A''(x) = 8(-2) = -16 < 0$. So it’s a local max by SDT.
- $A(0) = A(3) = 0$, $A\left(\frac{3}{2}\right) = 8\left(-\frac{9}{4} + \frac{9}{2}\right) = 18$.
- So the dimensions are $3 \times 6$.

**In General**

1) Draw picture.
2) What do you want to maximize/minimize? Find a formula for it.
3) Use the constraints in the problem to write the formula from (2) in terms of one variable only.
4) Determine the relevant domain for the problem.
5) Determine the absolute max/min as before.

**Example**

Suppose we’re to inscribe a cylinder in a right circular cone height 8, base radius 5. Find the dimensions of the cylinder, maximizing volume.
Want to maximize the volume.

Volume = \( \pi x^2 y \).

\[ V(x) = \pi x^2 \left( -\frac{8}{5}x + 8 \right) = \frac{8}{5} \pi (-x^3 + 8x^2) \]

Relevant domain: \([0, 5]\).

\[ V'(x) = \frac{8}{5} \pi (-3x^2 + 10x) = \frac{8}{5} \pi (-3x + 10) = 0 \Rightarrow x = \frac{10}{3} \]

\[ V''(x) = \frac{8}{5} \pi (-6x) < 0 \text{, which is local max by SDT.} \]

\[ V(0) = V(5) = 0 \text{, } V\left(\frac{10}{3}\right) = \frac{800}{27} \pi. \text{ So the absolute max is } \frac{800}{27} \pi. \]

So the dimensions are: radius \( \frac{10}{3} \), height \( \frac{8}{3} \).

---

**Lecture #21 – Tuesday, November 18, 2003**

**Concavity**

**Discussion of Concavity: About Second Derivative**

- Rough example: From economics, the cost function for producing \( x \) widgets \( c(x), \frac{dc}{dx}(100) = \text{cost of producing the next "widget".} \) The second derivative is measuring how fast \( \frac{dc}{dx} \) is changing.

**Picture**

---

**Definition: Concavity**

Let \( f \) be differentiable on an open interval \( I \). Then \( f \) is **concave up** if \( f'' \) is increasing on \( I \), and **concave down** if \( f'' \) is decreasing on \( I \).
**Definition: Point of Inflection**

Let \( f \) be continuous at \( c \). Then \( c \) is a point of inflection if \( \exists \delta > 0 \) such that \( f \) is concave in one sense on \((c-\delta, c)\), and \( f \) is concave in the other sense on \((c, c+\delta)\).

**Example**

\[ f(x) = x^3 \]
- \( f'(x) = 3x^2 \), and 0 is a point of inflection.

![Graph of f(x) = x^3](image)

**Theorem**

Let \( f \) be twice differentiable on open interval \( I \).

1) If \( f''(x) > 0 \), then \( f \) is concave up.
2) If \( f''(x) < 0 \), then \( f \) is concave down.

**Proof**

- The same as when we proved that if \( f'(x) > 0 \) on \( I \), then \( f \) is increasing. Now use \( g = f' \).

- How to find points of inflection? Come up with a list of possible points of inflection.

**Theorem**

If \( (c, f(c)) \) is a point of inflection, then either:

1) \( f'''(c) = 0 \)
2) \( f'''(c) \) DNE
- This is analogue of the theorem for local extreme values.
- Warning: Just as critical points don’t need to be local extrema, just because \( f'''(c) = 0 \) does not mean \( (c, f(c)) \) is a point of inflection.

**Example**

- \( f(x) = x^4 \)
- \( f'(x) = 4x^3 \)
- \( f''(x) = 12x^2 \)
- At \( x = 0 \), \( f'''(c) = 0 \), but it’s not a point of inflection.
Proof

- Assume \((c, f(c))\) is a point of inflection. Assume \(f\) is concave up on the left and concave down on the right.
- By definition, \(f'\) is increasing on the left on \((c-\delta, c)\), \(f'\) is decreasing on the right on \((c, c+\delta)\).
- Assume \(f''\) exists. Then \(f'\) is continuous. So \(f''(x) > 0\) on \((c-\delta, c]\) and \(f''(x) < 0\) on \([c, c+\delta)\).
- The only other possibility is that \(f''(c)\) DNE.

Q.E.D.

Example

Find intervals of concavity and points of inflection for \(f(x) = x + \cos x\) on \([0, 2\pi]\).

- \(f'(x) = 1 - \sin x\), \(f''(x) = -\cos x\).
- Possible points of inflection: \(x = \pi, \frac{3\pi}{2}\).
- Look at intervals:

Lecture #22 – Thursday, November 20, 2003

HORIZONTAL ASYMPOTOTES

- “Limits of the function at \(\pm\infty\).”
- Now we care about the behaviour of \(f\), regardless of weather it goes to \(\pm\infty\).

Example

- \(f(x) = \frac{3x+1}{x}\).
- We want to say “\(\lim_{x \to \infty} f(x) = 3\)”.

Definition

\(\lim_{x \to \infty} f(x) = L\) if \(\forall \varepsilon > 0\), \(\exists \delta > 0\) so that if \(x > k\), then \(|f(x)-L| < \varepsilon\). If this is true, then the line \(y = L\) is called the horizontal asymptote.
Example

Prove that \( \lim_{x \to \pm \infty} \frac{3x+1}{x} = 3 \).

- Given \( \varepsilon > 0 \), we need to find \( k > 0 \) so that if \( x > k \), we want \( \left| \frac{3x+1}{x} - 3 \right| < \varepsilon \).

- Choose \( k = \frac{1}{\varepsilon} \).

Q.E.D.

- Notice: \( \lim_{x \to \pm \infty} \frac{3x+1}{x} = \lim_{x \to \pm \infty} \frac{x\left(3 + \frac{1}{x}\right)}{x} \).

Examples: Techniques for finding horizontal asymptotes

1) \( \lim_{x \to \pm \infty} \frac{x+1-\sqrt{x}}{x^2+2x+1} = \lim_{x \to \pm \infty} \frac{x\left(1+\frac{1}{x} - \frac{1}{\sqrt{x}}\right)}{x^2\left(1+\frac{2}{x} + \frac{1}{x^2}\right)} = 0 \).

2) \( \lim_{x \to \pm \infty} \frac{2x^3+3x+7}{3x^3+10x-5} = \lim_{x \to \pm \infty} \frac{x^3\left(2 + \frac{3}{x^3} + \frac{7}{x^3}\right)}{x^3\left(3 + \frac{10}{x^2} - \frac{5}{x^3}\right)} = \frac{2}{3} \).

General Technique

- For \( R(x) = \frac{a_n x^n + \ldots + a_0}{b_k x^k + \ldots + b_0} \), \( \lim_{x \to \pm \infty} R(x) = \begin{cases} \pm \infty & \text{if } n > k \\ \frac{a}{b} & \text{if } n = k \\ 0 & \text{if } n < k \end{cases} \).

Vertical Asymptotes

- Now, let’s consider the possibility that \( \lim_{x \to c^+} f(x) = \pm \infty \) or \( \lim_{x \to c^-} f(x) = \pm \infty \).
Definition

The line \( x = c \) is a \textit{vertical asymptote} for \( f \) if any of these happen:

1) \( \lim_{x \to c} f(x) = \pm \infty \)
2) \( \lim_{x \to c^-} f(x) = \pm \infty \)
3) \( \lim_{x \to c^+} f(x) = \pm \infty \)

Precise Definition (For 2)

\( \forall N > 0, \exists \delta > 0 \) so that if \( c < s < c + \delta \) then \( f(s) > N \).

Example

Prove that \( \lim_{x \to 1^+} \frac{1}{x-1} = +\infty \).

\begin{itemize}
  \item Given \( N > 0 \), we want \( \frac{1}{x-1} > N \) if \( 1 < x < 1 + \delta \) for some \( \delta \).
  \item Since \( 1 < x < 1 + \delta \), then \( x - 1 < \delta \). Choose \( \delta = \frac{1}{N} \).
  \item Now, if \( x - 1 < \delta \) means \( \frac{1}{x-1} > N \).
\end{itemize}

Q.E.D.

\textbf{VERTICAL TANGENTS AND CUSPS}

Example

\( y = x^3 \)

\begin{itemize}
  \item Example of vertical tangent because the derivative “becomes \( \infty \)."
\end{itemize}

Example

\( y = x^2 \)

\begin{itemize}
  \item Example of vertical cusp.
\end{itemize}

Definition

Graph of \( f \) has a vertical tangent at \( (c, f(c)) \) if \( \lim_{x \to c^+} f'(x) = \pm \infty \).
**Definition**

Graph of \( f \) has a vertical cusp at \((c, f(c))\) if:

- \( \lim_{{x \to c^-}} f'(x) = \infty \), \( \lim_{{x \to c^-}} f'(x) = -\infty \)
- \( \lim_{{x \to c^+}} f'(x) = -\infty \), \( \lim_{{x \to c^+}} f'(x) = \infty \)

**Example**

- \( f(x) = x^3 \)

- Double check \((0,0)\) is a vertical cusp.
- We need to compare the slopes of \( f \) close to 0.
- \( f(x) = \frac{2}{3} x^{-\frac{1}{3}} = \frac{2}{3} \cdot \frac{1}{\sqrt[3]{x}} \).
- \( \lim_{{x \to 0^+}} \frac{2}{3} \cdot \frac{1}{\sqrt[3]{x}} = +\infty \), \( \lim_{{x \to 0^-}} \frac{2}{3} \cdot \frac{1}{\sqrt[3]{x}} = -\infty \).
- So \((0,0)\) is a vertical cusp.

**CURVE SKETCHING**

**Procedure**

1) Find domain of \( f \), behaviour at endpoints and \( \pm \infty \).
2) Intercepts (both \( y \) and \( x \)).
3) Symmetry and/or periodicity.
4) Use \( f' \): look for critical points, FDT, local extrema.
5) Use \( f'' \): concavity and points of inflection.
6) Plot relevant points and sketch.

**Example**

Sketch the graph of \( f(x) = \frac{1}{4} x^4 - 2x^2 + \frac{7}{4} \).

- Domain of \( f = (-\infty, \infty) \).
- Look at: \( \lim_{{x \to \infty}} = +\infty \), \( \lim_{{x \to -\infty}} = +\infty \).
- \( y \)-intercept: \( \left\{ 0, \frac{7}{4} \right\} \).
- \( x \)-intercept: Solve \( \frac{1}{4} x^4 - 2x^2 + \frac{7}{4} = 0 \iff x^4 - 8x^2 + 7 = 0 \iff (x^2 - 7)(x^2 - 1) = 0 \). So \( x \)-intercepts are at \( x = 1, -1, \sqrt{7}, -\sqrt{7} \).
- Symmetry: \( f(x) \) is even, so it is enough to graph \( f \) on \([0, \infty)\).
- Use \( f' \): \( f'(x) = x^3 - 4x = x(x^2 - 4) = x(x + 2)(x - 2) \).
  - Critical points: \( x = 0, 2, -2 \).
  - Sign of \( f' \) at critical points:
    - \( x = -2 \) is a min.
    - \( x = 0 \) is a max.
    - \( x = 2 \) is a min.
• Local minimums at \( \left( 2, -\frac{9}{4} \right) \) and \( \left( -2, -\frac{9}{4} \right) \).

• Local maximum at \( \left( 0, \frac{7}{4} \right) \).

• Use \( f'' \): 
  \[ f''(x) = 3x^2 - 4 = 3 \left( x^2 - \frac{4}{3} \right) = 3 \left( x + \frac{2}{\sqrt{3}} \right) \left( x - \frac{2}{\sqrt{3}} \right) . \]

• Possible points of inflection at \( x = \frac{2}{\sqrt{3}}, -\frac{2}{\sqrt{3}} \)

  
  Sign of \( f'' \): 
  
  \[
  \begin{array}{c|c|c}
  & + & - & + \\
  \hline
  \frac{2}{\sqrt{3}} & \frac{2}{\sqrt{3}} & \frac{2}{\sqrt{3}} & \frac{2}{\sqrt{3}} \end{array}
  \]

• Points of inflection: \( \left( -\frac{2}{\sqrt{3}}, -\frac{17}{36} \right) \), \( \left( \frac{2}{\sqrt{3}}, \frac{17}{36} \right) \).

Example

Sketch the graph of \( f(x) = \frac{x^2 - 3}{x^3} = x^{-1} - 3x^{-3} \).

• Domain of \( f = (-\infty, 0) \cup (0, \infty) \).
  
  \[ \lim_{x \to 0^+} \frac{x^2 - 3}{x^3} = -\infty, \quad \lim_{x \to 0^-} \frac{x^2 - 3}{x^3} = +\infty. \]

• Look for critical points: 
  \[ f'(x) = -x^{-2} + 9x^{-4} = \frac{9 - x^2}{x^4} . \]
  
  • Careful: Critical points are at \( x = 3, -3 \), and not \( x = 0 \) because 0 not in domain.

Example

\( f(x) = \sin 2x - 2 \sin x \)

• Domain: \( (-\infty, \infty) \).

• No asymptotes or limits as \( x \to \pm\infty \).

• \( f \) is odd and periodic.

• It's enough to graph it on \([0, \pi]\).
Lecture #23 – Tuesday, November 25, 2003

NEWTON-RAPHSON METHOD

- This is a way of approximate solutions to equations of the form \( f(x) = 0 \).
- “Math Fact”: General method for finding roots, for example to polynomial equations, is not known, so approximation methods are required.
- Reminder: Geometric interpretation for derivatives is “rate of change”.

\[
\frac{f(x + h) - f(x)}{h} \approx f'(x) \cdot h
\]

- The Point: As \( h \) gets small, \( f(x + h) - f(x) \) is close to \( f'(x) \cdot h \).
  - \( f(x + h) - f(x) \): increment of \( f \) from \( x \) to \( x + h \) (\( \Delta f \))
  - \( f'(x) \cdot h \): differential of \( f \) at \( x \) with increment \( h \) (\( df \))
  - \( \Delta f \equiv df \) for small \( h \)

**Example**

Approximate \( \sqrt{2} \).

- In this situation, \( f(x) = \sqrt{x} \) and \( x + h = 2 \).
- \( f(x + h) - f(x) \equiv f'(x) \cdot h \leftrightarrow f(x + h) \equiv f'(x) \cdot h + f(x) \).
- Let’s pick \( x = \frac{16}{9} \).

\[
f'(x) = \frac{1}{2 \sqrt{x}}. \text{ So } f\left(\frac{16}{9}\right) = \frac{16}{9} \cdot \frac{4}{3} = \frac{16}{9} \text{ and } f\left(\frac{16}{9}\right) = \frac{1}{2} \cdot \frac{3}{4} = \frac{3}{8}.
\]

\[
f\left(\frac{16}{9}\right) + f\left(\frac{16}{9}\right) \cdot \left(2 - \frac{16}{9}\right) = \frac{1}{3} + \frac{2}{12} = \frac{17}{12} = 1.417.
\]

**Newton-Raphson Method**

- A little more sophisticated – use differentials at each step of the algorithm.

\[
x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}
\]

- Algorithm in “picture”:
  - Start with some point \( x_1 \).
  - Draw tangent to \( f \) at \((x_1, f(x_1))\) and find the \( x \)-intercept.
  - Call that \( x_2 \).
  - Repeat as necessary.
What Is $x_2$?

- The equation for the tangent line is $y - f(x_1) = f'(x_1)(x - x_1)$.
- At the $x$-intercept $x_2$, we must have:
  
  \[
  0 - f(x_1) = f'(x_1)(x_2 - x_1) = f'(x_1)x_2 - f'(x_1)x_1 \Rightarrow x_2 = \frac{f(x_1)x_1 - f(x_1)}{f'(x_1)} = x_1 - \frac{f(x_1)}{f'(x_1)}.
  \]

- So in general: $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}.$

Various Pitfalls

- At any $x_n$, if $f'(x_n) = 0$, tough luck!
- No $x$-intercept.

- Concavity issue: $x_3$ is further away from $c$ than $x_2$!

- Fact (without proof): If $f$ is twice differentiable and if $f(x) \cdot f''(x) > 0$ on an interval joining $x$ to $c$, then Newton-Raphson method works.

Lecture #24 – Thursday, November 27, 2003

Example

Approximate $\sqrt{2}$.

- Take $f(x) = x^2 - 2$. Find a root.
- Use IVT: $f(0) = -2 < 0$, $f(2) = 2 > 0$. 

• Take derivative: \( f'(x) = 2x \).

• Take \( x_1 = 2 \): \( x_2 = 2 - \frac{2}{4} = \frac{3}{2} \).

• \( x_3 = \frac{3}{2} \cdot \frac{1}{4} = \frac{3}{2} \cdot \frac{1}{12} = \frac{17}{12} \).

• \( x_4 = \frac{17}{12} - \frac{\frac{17}{12}}{\frac{17}{12}} = \frac{17}{12} - \frac{1}{12} = \frac{6}{17} = \frac{3462}{144 \cdot 17} = 1.41422 \).

L'HÔPITAL’S RULES

• These are rules that help you evaluate limits that are of the form “\( \frac{0}{0} \)” or “\( \frac{\infty}{\infty} \).”

Theorem: L'Hôpital’s Rules

Suppose \( f(x) \) and \( g(x) \) both have limit 0 as \( x \) approaches \( c^+, c^-, c, \infty, \) or \(-\infty\). If the limit of \( \frac{f'(x)}{g'(x)} = L \) approaches the same value (\( c^+, c^-, c, \infty, -\infty \)), then the limit \( \frac{f(x)}{g(x)} = L \).

• Note: \( L \) is allowed to be “\( \pm \infty \)” – i.e. if \( \frac{f'(x)}{g'(x)} \) has an asymptote, then so does \( \frac{f(x)}{g(x)} \).

Examples

1) \( \lim_{x \to 4} \frac{\sqrt{x} - 2}{x - 4} = \lim_{x \to 4} \frac{1}{2} \cdot \frac{1}{\sqrt{x}} = \frac{1}{4} \).

2) \( \lim_{x \to 4} \frac{1 - x^2}{1 - x^2} = \lim_{x \to 4} \frac{-2x}{-3x^2} = \frac{2}{3} \).

• WARNING: You must check at all times that you can apply the l'Hôpital’s Rule – i.e. you have a “\( \frac{0}{0} \)” In particular, be careful when you apply l'Hôpital’s Rule several times.

• To prove l'Hôpital, we’ll need Cauchy MVT.

Theorem: Cauchy Mean Value theorem

Suppose \( f, g \) are differentiable on \( (a, b) \) and continuous on \( [a, b] \). If \( g' \neq 0 \) for all points in \( (a, b) \), then there exists \( r \) in \( (a, b) \) so that \( \frac{f'(r)}{g'(r)} = \frac{f(b) - f(a)}{g(b) - g(a)} \).

• Notice: If \( g(x) = x \), the Cauchy MVT is the MVT – \( g'(x) = 1 \), so \( f'(r) = \frac{f(b) - f(a)}{b-a} \).
• Notice: this is promising; it says something about the ratios of derivatives relating to ratios with the functions.

Picture

![Graph of functions f and g with points a and b, and ratios f(b) - f(a) / g(b) - g(a) highlighted.]

• Assume \( f(a) = g(a) = 0 \).
• Somewhere between \((a, b)\), the ratio of the instantaneous rates of change has to equal to the average rates of change.

Proof
• The proof will use Rolle’s Theorem.
• Let’s rewrite: \( \frac{f'(r)}{g'(r)} = \frac{f(b) - f(a)}{g(b) - g(a)} \Leftrightarrow f'(r)(g(b) - g(a)) - g'(r)(f(b) - f(a)) = 0 \).
• Want: Some \( r \) where \( f'(r)(g(b) - g(a)) - g'(r)(f(b) - f(a)) = 0 \), but LHS looks like a derivative.
• Consider the function \( G(x) = (f(x) - f(a))(g(b) - g(a)) - (g(x) - g(a))(f(b) - f(a)) \).
• So \( G(a) = G(b) = 0 \). \( G \) is continuous and differentiable because \( f \) and \( g \) are.
• Rolle’s Theorem says there is an \( r \) in \((a, b)\) such that \( G'(r) = 0 \).
• So \( f'(r)(g(b) - g(a)) = g'(r)(f(b) - f(a)) \).
• Since \( f'(r)(g(b) - g(a)) \neq 0 \) and \( g'(r)(f(b) - f(a)) \neq 0 \), we can divide. We get \( \frac{f'(r)}{g'(r)} = \frac{f(b) - f(a)}{g(b) - g(a)} \).

Q.E.D.

Proof of L'Hôpital (case \( \to c^* \))
• Assume \( \lim_{x \to c^*} f(x) = \lim_{x \to c^*} g(x) = L \).
• So \( f \) and \( g \) are differentiable on some \((c, c + h)\). Also \( g' \neq 0 \).
• Cauchy MVT says \( \exists r_h \) so that \( \frac{f'(r)}{g'(r)} = \frac{f(c + h) - f(c)}{g(c + h) - g(c)} = \frac{f(c + h)}{g(c + h)} \).
• Taking limit as \( h \to 0 \), \( \lim_{h \to 0} \frac{f(r_h)}{g(r_h)} = \lim_{h \to 0} \frac{f(c + h)}{g(c + h)} \).
• LHS limit is \( L \), because \( r_h \) is in \((c, c + h)\). So RHS limit is also \( L \).

Q.E.D.

Example
\[
\lim_{x \to 0} \frac{\cos x - 1 + \frac{x^2}{2}}{x^4} = \lim_{x \to 0} \frac{\sin x + x}{4x^3} = \lim_{x \to 0} \frac{-\cos x + 1}{12x^2} = \lim_{x \to 0} \frac{\sin x}{24x} = \lim_{x \to 0} \frac{\cos x}{24} = \frac{1}{24}
\]
Lecture #25 – Tuesday, December 2, 2003

Examples

1) \[ \lim_{x \to 0} \frac{\sqrt{a+x} - \sqrt{a-x}}{x} = \lim_{x \to 0} \frac{1}{2} \frac{1}{\sqrt{a+x}} + \frac{1}{2} \frac{1}{\sqrt{a-x}} = \frac{1}{\sqrt{a}}. \]

2) \[ \lim_{x \to 0^+} \frac{\sqrt{x}}{\sin \sqrt{x} + \sqrt{x}} = \lim_{t \to 0^+} \frac{t}{\sin t + t} = \lim_{t \to 0^+} \frac{1}{\cos t + 1} = \frac{1}{2}. \]

L'Hôpital For “Infinity Over Infinity”

Suppose \( \lim_{x \to c^-} f(x) = \lim_{x \to c^+} g(x) = \infty \) and \( \lim_{x \to c^-} g(x) = \lim_{x \to c^+} g(x) = L \). If \( \lim_{x \to c^-} f'(x) = \lim_{x \to c^+} f'(x) = L \), then \( \lim_{x \to c^-} \frac{f(x)}{g(x)} = \lim_{x \to c^+} \frac{f(x)}{g(x)} = \frac{1}{L} \).

Examples

1) \[ \lim_{x \to \infty} \frac{\sqrt{1+x^2}}{x^2} = \lim_{x \to \infty} \frac{1}{2} \frac{1}{\sqrt{1+x^2}} \cdot 2x = 0. \]

2) \[ \lim_{x \to \infty} x \cdot \sin \left( \frac{1}{x} \right) \]

- There are two ways to rewrite it as a quotient: \( \lim_{x \to \infty} \frac{\sin \left( \frac{1}{x} \right)}{\frac{1}{x}} \) or \( \lim_{x \to \infty} \frac{x}{\sin \left( \frac{1}{x} \right)} \).

- Could also do \( \lim_{x \to \infty} x \cdot \sin \left( \frac{1}{x} \right) = \lim_{x \to \infty} \frac{\sin \left( \frac{1}{x} \right)}{\frac{1}{x}} = \lim_{y \to 0} \frac{\sin(y)}{y} = 0 \).

3) Limits of the form “\( \infty - \infty \)”: \( \lim_{x \to \frac{\pi}{2}} (\tan x - \sec x) = \lim_{x \to \frac{\pi}{2}} \left( \frac{\sin x - 1}{\cos x} \right) = \lim_{x \to \frac{\pi}{2}} \left( \frac{\cos x}{-\sin x} \right) = 0. \)

More Curve Sketching

Example

Sketch the graph of \( f(x) = \frac{x}{x^2 - 1} \).

- Domain: \( (-\infty, -1) \cup (-1, 1) \cup (1, \infty) \).

- Behaviour at endpoints:
  - \( \lim_{x \to \infty} \frac{x}{x^2 - 1} = 0 \) “coming from below”.
\[ \lim_{x \to \infty} \frac{x}{x^2 - 1} = 0 \]  “coming from above”.
\[ \lim_{x \to -1} \frac{x}{x^2 - 1} = \lim_{x \to -1} \frac{x}{x - 1} \cdot \frac{1}{x + 1} = -\infty, \quad \lim_{x \to -1} \frac{x}{x^2 - 1} = \lim_{x \to -1} \frac{x}{x - 1} \cdot \frac{1}{x + 1} = \infty. \]
\[ \lim_{x \to -1} \frac{x}{x^2 - 1} = \lim_{x \to -1} \frac{x}{x + 1} \cdot \frac{1}{x - 1} = -\infty, \quad \lim_{x \to -1} \frac{x}{x^2 - 1} = \lim_{x \to -1} \frac{x}{x + 1} \cdot \frac{1}{x - 1} = \infty. \]

- Use \( f'(x) = \frac{(x^2 + 1)}{(x^2 - 1)^2} \).
- Since \( f'(x) \neq 0 \) for all \( x \in \text{domain}(f) \), there are no critical points.

- Use \( f''(x) = \frac{2x(x^2 + 1)}{(x^2 - 1)^3} \).

\[ f'' \begin{array}{c|c|c|c|c} - & + & - & + \\ \hline \text{down} & -1 & \text{up} & 0 & \text{down} & \text{up} \end{array} \]

Sketch:
